(57) **ABSTRACT**

Methods, systems, and associated devices for supplying support members to a product loading station, loading, and automatically removing loaded members therefrom include: (a) advancing in spaced-apart relationship, a plurality of carrier members having opposing first and second ends and an associated width and length, along a selected travel path to a loading station; (b) straddling elongated product over each respective carrier member at the loading station so that portions of the elongated product are serially draped over the corner member along a length thereof, the straddling being carried out so that certain lengths of the elongated product hang from opposing sides of the carrier member; and (c) advancing the carrier members loaded with the straddled product downstream of the loading station.

RELATED APPLICATIONS

This application claims priority from U.S. Provisional Patent Application Ser. No. 60/362,375 filed Mar. 7, 2002, and U.S. Provisional Patent Application Ser. No. 60/370,874 filed Apr. 8, 2002, the contents of which are hereby incorporated by reference as if recited in full herein.

FIELD OF THE INVENTION

The present invention relates to movement or transfer of product within processing facilities and is particularly suitable for loading and automatically loading and positioning rods or product support members in food preparation and production systems that include extruders or stuffers.

BACKGROUND OF THE INVENTION

Conventionally, extruded or stuffed food products such as pasta, dough, and meats such as hot dogs, links, or sausages, can be processed so that the desired food material is extruded or mixed and prepared, then propelled through a “stuffer machine” that includes a stuffing nozzle, extrusion machine, or co-extrusion machine. In operation, in certain food items, as the food moves through the stuffing nozzle or extrusion head, a natural or synthetic casing is disposed about and/or deposited or wrapped around the external surface of the food material to form a continuous length of encased elongated food product. To form certain products (such as hotdogs and sausages), the casing can be twisted, tied, nipped, and/or crimped at certain intervals, forming a chain-like string or strand of encased food product. Extruders and co-extruders are available from various commercial manufacturers including, but not limited to, Townsend Engineering Co., located in Des Moines, Iowa. Stuffers are available from various commercial manufacturers including, but not limited to, HITEC Food Equipment, Inc., located in Elk Grove Village, Ill., Townsend Engineering Co., located in Des Moines, Iowa, Robert Reiser & Co., Inc., located in Canton, Mass., and Handtmann, Inc., located in Buffalo Grove, Ill. Exemplary stuffer and/or linker apparatus are also described in U.S. Pat. Nos. 5,788,563; 5,480,346; 5,049,108; and 4,766,645. The contents of these patents are hereby incorporated by reference as if recited in full herein.

After stuffing or extruding, the encased elongated food product is expelled from the stuffer or extruder via a material discharging exit port. FIG. 1A illustrates a conventional stuffer **10** and stuffer material discharge port **10p**. The stuffer discharge port **10p** is positioned proximate a “linker” or looping and transferring device **15** (FIG. 1B) that rotates an endless chain of hooks **15h** about the discharge port **10p**. Generally described, the material discharge port **10p** is configured so that, during operation, the product is expelled and directed so that the traveling hooks, which serially travel to be adjacent the discharge port **10p**, catch a portion of the length of the product, with the result that the product forms loops on the hooks at certain intervals. More specifically, certain devices are configured so that the hooks **15h** travel to the discharge port **10p** and the discharge port **10p** discharges into a downwardly inclined channel that directs the elongated food downward and, as the hooks turn to face the discharged food, the hooks sequentially individually reach

out to grasp the product at certain intervals. Other devices propel the encased product onto hooks that rotate thereabout (typically under) to catch the product at certain intervals to transfer the encased material onto the transfer device. The hooks **15h** then suspend the product in a looped configuration (hanging in a vertical orientation) as shown in FIG. 1B, with each hook **15h** supporting a single loop of product.

FIG. 1C illustrates a slightly different prior art stuffer **10** and associated linker **15** with hooks that are oriented to rotate in a different plane from that shown in FIG. 1A (i.e., a vertical plane rather than a horizontal plane). In addition, in this prior art stuffer/linker, the discharge port **10p** terminates into a short expanse of tubing that forms a rotating discharge nozzle **10r**. The rotating nozzle **10r**, again, propels the extruded encased product onto the hooks **15h**.

After the product is suspended on the hooks **15h**, a rod or stick is typically manually inserted through the suspended looped product above the hooks and below the upper looped portion of the food, and the product is manually lifted up and off the hooks **15h** and transferred to a trolley, oven, or other food processing station.

In view of the foregoing, there is a need to provide automated processing systems that can improve the production process to facilitate the loading of food receiving members such as sticks and/or reduce the need for manual labor to load sticks.

SUMMARY OF THE INVENTION

Certain embodiments of the present invention provide automated loading, positioning and removal systems of carrier members with elongate product that can automate the loading of empty and/or the removal or subsequent downstream transfer of carrier members loaded with elongate product. The carrier members may be elongated members, such as bars, rods or sticks. The system may employ carrier members that are the same or different configurations, sizes, or lengths. The system may also include a packing mechanism to arrange the suspended elongate product so that suspended regions reside more closely together on the carrier member, thereby providing a high-density product distribution arrangement.

In particular embodiments, the carrier members can be food support members that are portable and adapted to hold, carry, and transfer, away from the loading station (such as proximate an extruder/stuffer), an elongated, extruded, and/or stuffed product. The food support members can be used to directly capture and hold the product at the extruder/stuffer discharge port and then to deliver the product to a trolley or desired workstation or other desired equipment or component.

In certain embodiments, the positioning, advancing and/or removal systems provided by the present invention can be configured with a carousel portion that can substantially continuously provide a series of unloaded (empty) rods to a loading station and then automatically take-away the rods from the loading station when they are loaded with straddled, cut, bights or looped product. The positioning and removal systems may be configured as endless systems with a fixed travel path associated with a predetermined travel track that, in operation, continuously serially advances the rods.

Certain embodiments are directed to methods for supplying and loading carrier members at a loading station comprising a winding mechanism with an associated winder arm. The method includes: (a) advancing in spaced-apart relationship, a plurality of carrier members having opposing

first and second ends and an associated width and length, along a selected travel path to a loading station; (b) presenting, in serial order, the carrier members to the loading station in a substantially horizontal orientation; (c) discharging elongated product from a winder arm that moves in a selected pattern about the carrier member at the loading station; (d) straddling elongated product over each respective carrier member at the loading station responsive to the discharging step so that portions of the elongated product are serially draped over the carrier member along a length thereof, the straddling being carried out so that certain lengths of the elongated product hang from opposing sides of the carrier member; and (e) advancing the carrier members loaded with the straddled product away from the loading station along the selected travel path to cause the loaded members to travel downstream of the loading station.

The arm can be configured to repetitively translate in a desired loading pattern so as to allow the elongated item(s) to drape over the carrier member in straddled arrangements such as in loops, bights, or discrete lengths.

In certain embodiments, the winder arm can be configured to move a sufficient vertical and/or horizontal distance so as to travel above and below and/or side to side about a suitably aligned rod or carrier member that can be automatically located in the loading zone during the transfer or loading by the automated positioning and takeaway system.

The arm may be configured to move one or more of: up and down, forward and rearward, and/or back and forth across the aligned carrier member. In certain other embodiments, the arm can rotate in a substantially circular, oval, elliptical, or other desired motion. The generated motion may be a closed loop path that has two different directions of travel, such as a motion that includes both x and y axis directional components. The rod or food transfer or support member may be configured to automatically unidirectionally (linearly) translate forward as the arm translates (moved either forward or backward toward or away from the stuffer discharge port) so that the automated winder can wrap or drape discrete lengths or continuous lengths of bights or loops of the released product starting at one end portion of the carrier member and terminating at the opposing end portion so that a major portion, and in certain embodiments, substantially the entire length (or a desired length), of the carrier member is covered with a discontinuous lengths of discrete straddled product and/or a continuous length of straddled, draped and/or looped product.

In certain embodiments, the winder can load discontinuous lengths of product, shown as a plurality of cut lengths of elongated product that are straddled onto and/or draped over the support member. In other embodiments, the winder loads a continuous length of product onto the carrier member. Combinations of the loading techniques can also be employed. The product can be loaded onto the support member such that the strands have substantially the same suspended lengths, or to have varying lengths, along the same or different rods or support members.

The rod or carrier member can be one, or more, portable stick members, upon which, the wrapped continuous length product can be suspended in a looped or straddled arrangement, each loop or draped straddle segment can have a substantially uniform length or different lengths.

Other embodiments are directed to systems for supplying support members to a product loading station, loading the members, and automatically removing loaded support members therefrom. The systems include: (a) advancing means for advancing, in serial order and in spaced-apart relationship, a plurality of elongated support members having

opposing first and second ends and an associated length, along a selected travel path to a loading station; (b) loading means for straddle loading each of the elongated support members individually with a respective length or lengths of elongated product formed into multiple loops, bights, or a plurality of discrete lengths of elongated product at the loading station; (c) advancing means for advancing the loaded elongated support members away from the loading station along the selected travel path to cause the loaded elongated support members to travel downstream of the loading position; and (d) packing means for moving adjacent segments of straddled product closer together on the carrier member to thereby allow increased density loading of the product on the carrier member.

In other embodiments, an automated support member supply, load, and removal system includes a supply and removal system that includes a central platform member; a travel track mounted to the platform member that, in operation, is configured to advance continuously about an endless path about the platform member; and a plurality of mounting brackets, each individually mounted to said travel track in spaced apart intervals, the mounting brackets being configured to travel along the endless path. The system also includes a plurality of elongated support members, each having an end portion configured to attach to a respective mounting bracket of the supply and removal system. The system additionally includes a loading station positioned in cooperating alignment with the supply and removal system, and the loading station comprising. The loading station includes a winder arm with a discharge end portion, the winder arm defining a floor for directing elongated food product to travel thereover and exit at the discharge end portion; and a winding mechanism operably associated with the winder arm. In operation, the winding mechanism is configured to move the winder arm in a predetermined travel path.

Additional embodiments are directed to an automated food handling system. The system includes: (a) a plurality of elongated support members having a length and sized and configured to hold multiple loops, bights of an elongated food product thereon and/or multiple discrete lengths of draped elongated product thereon; (b) an automated winder with a winder arm configured to be cooperatively positioned and aligned with the discharge port of an extrusion and/or stuffer device configured to discharge-elongated food product therefrom, the automated winder comprising; and (c) an automated positioning and advancing system for substantially continuously presenting and positioning in serial order a respective one of the plurality of elongated support members to the winding arm so that the winding arm is positioned in spaced apart cooperating alignment with the elongated support member and is able to load the support members with a plurality of loops or discrete lengths of the elongated food product.

The automated winder can include: (a) an elongated arm having an associated length that is about equal to or greater than the length of the elongated support member, said elongated arm having opposing first and second end portions, wherein, in position, said first end portion is adapted to receive the elongated product thereon from the extrusion and/or stuffer device, wherein said second end portion is configured to release the elongated product therefrom after the product travels greater than a major portion of the length of the arm in a direction that is away from the extrusion and/or stuffer device; and (b) a winding mechanism attached to said elongated arm, said winding mechanism being configured to cause said elongated arm to travel repetitively in

5

a desired motion so that, in operation, the winding mechanism causes the elongated product to individually travel about one of the support members as it is released from the second end portion of the arm.

In certain embodiments, the automated positioning and advancing system is configured to continuously sequentially and serially present the plurality of support members so that each is aligned with the arm of the winder for a desired interval of time so as to successively substantially continuously transfer and wind elongated product onto each of the plurality of support members.

In certain embodiments, the selected travel path defined by the positioning and advancing system includes a linear portion, and the loading step is carried out while the respective elongated support member being loaded is continuously advancing forward along the linear portion of the selected travel path. The travel path may also include a curvilinear portion.

Still other embodiments are directed to an automated loading system. The system includes: (a) a plurality of elongated support members having a length and sized and configured to hold multiple loops or a plurality of discrete lengths of an elongated product thereon; (b) an automated winder configured to be cooperatively positioned and aligned with the discharge port of an extrusion/stuffer device configured to discharge-elongated product therefrom, the automated winder comprising; and (c) an automated apparatus for continuously presenting and positioning in serial order a respective one of the plurality of elongated support members to the winding arm so that the winding arm is positioned in spaced apart cooperating alignment with the elongated support member and is able to load the support members with a plurality of loops of the elongated product. The automated winder includes: (a) an elongated arm having an associated length that is about equal to or greater than the length of the elongated support member, said elongated arm having opposing first and second end portions, wherein, in position, said first end portion is adapted to receive an elongated product thereon from the extrusion device, wherein said second end portion is configured to release the elongated item therefrom after the item travels greater than a major portion of the length of the arm in a direction that is away from the extrusion/stuffer device; and (b) a winding mechanism attached to said elongated arm, said winding mechanism being configured to cause said elongated arm to travel repetitively in a desired motion so that, in operation, the winding mechanism causes the elongated product to wind serially about one of the support members as it is released from the second end portion of the arm.

In certain embodiments, the automated apparatus continuously translates the elongated support member away from the extrusion/stuffer device during operation so as to distribute multiple loops or bights or a plurality of discrete lengths of suspended product over a desired length of the support member.

In particular embodiments, the carrier member is linearly translated forward away from the extrusion or stuffer device during loading so as to receive the wound product so that it is distributed over a desired length of the support member. The wound product may be arranged in substantially uniform looped or draped lengths of product hung or suspended from the carrier member. The system may be arranged so that over a desired time period, the winder is substantially continuously operated to load a plurality of support members that are serially aligned with the arm for a desired interval of time so as to successively transfer and wind elongated product thereon.

6

Further, in certain embodiments, the carrier member(s) is a stick or rod that can mount to conventional trolleys, rails, conveyors, railcars, drive tracks, and/or be used to support the elongated product at and/or through storage and/or the next active workstation that may be an oven, a smoker, a curer, packaging or other food preparation and/or processing station.

These and other objects and aspects of the present invention are explained in detail in the specification set forth below.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a perspective view of a prior art extruded food stuffer and associated linker or transferring and looping device.

FIG. 1B is an enlarged view of the looping hooks of the device shown in FIG. 1A showing an elongated extruded encased food product suspended thereon.

FIG. 1C is a perspective view of another prior art stuffer and linker.

FIG. 2A is a perspective view of a portion of an automated rod positioning system and loading station according to embodiments of the present invention.

FIG. 2B is a perspective view of a portion of an automated rod positioning system and loading station according to alternative embodiments of the present invention.

FIG. 3 is a schematic top view of an exemplary rod loading and/or positioning and removal system according to embodiments of the present invention.

FIGS. 4-9 are schematic top views of a sequence of operations illustrating the movement of a single rod along its predetermined travel path showing empty (FIGS. 4-6) and loaded (FIGS. 8 and 9) configurations or combinations thereof according to embodiments of the present invention.

FIG. 10A is a schematic top view of an alternative configuration of an automated positioning and removal system for supplying a continuous supply of empty rods for loading according to embodiments of the present invention.

FIG. 10B is a schematic top view of an alternative configuration of an automated positioning and removal system for supplying a continuous supply of empty rods for loading according to embodiments of the present invention.

FIG. 10C is a side view of a portion of a mounting configuration for a support member shown in FIG. 10B according to embodiments of the present invention.

FIG. 11A is a perspective view of a portion of an apparatus that can hold, advance, and concurrently position pairs of elongated support members according to embodiments of the present invention.

FIG. 11B is a perspective view of a portion of an apparatus that can hold, advance, and concurrently position pairs of elongated support members according to other embodiments of the present invention.

FIG. 11C is a perspective view of another alternative configuration of an elongated support member according to embodiments of the present invention.

FIG. 11D is a perspective view of an additional alternative configuration of an elongated support member according to embodiments of the present invention.

FIG. 12A is a perspective view of an additional alternative configuration of an elongated support member according to embodiments of the present invention.

FIG. 12B is a perspective view of an additional alternative configuration of an elongated support member according to embodiments of the present invention.

FIG. 12C is a cross-sectional view of an elongated support member according to embodiments of the present invention.

FIG. 12D is a cross-sectional view of another elongated support member according to embodiments of the present invention.

FIG. 12E is a cross-sectional view of an additional elongated support member according to embodiments of the present invention.

FIG. 13A is a side view of a loaded support member according to embodiments of the present invention.

FIG. 13B is a side view of a loaded support member according to embodiments of the present invention.

FIGS. 14A–14F are side views of a sequential series of operations used to pack product in close proximity according to embodiments of the present invention.

FIG. 15A is an enlarged front view of the end portion of the packing mechanism shown in FIGS. 14A–14F positioned relative to an underlying carrier member according to embodiments of the present invention.

FIG. 15B is an enlarged front view of the end portion shown in FIG. 15A with the device translated a distance down so as to engage with the carrier member in front of (or behind) a selected region of suspended elongated product according to embodiments of the present invention.

FIG. 16 is a side view of the device shown in FIGS. 14A–14F illustrating a more fully loaded carrier member with a plurality of closely spaced suspended regions held on the carrier member according to embodiments of the present invention.

FIG. 17A is a side view of a portion of an automated winder according to embodiments of the present invention.

FIG. 17B is a schematic illustration of an exemplary motion pattern of the arm of the automated winder of FIG. 17A according to embodiments of the present invention.

FIG. 17C is a side view of a portion of an automated winder similar to that shown in FIG. 17A illustrating a different winding pattern according to embodiments of the present invention.

FIG. 17D is a schematic illustration of an exemplary motion pattern of the arm of the automated winder of FIG. 17C according to embodiments of the present invention.

FIG. 17E is a side view of a portion of an automated winder similar to that shown in FIGS. 17A and 17C illustrating yet another different winding pattern according to embodiments of the present invention.

FIG. 18A is a schematic illustration of a portion of the automated winder illustrated in FIG. 17A showing the winder arm above the loading stick or receiving member.

FIG. 18B is a schematic illustration of a portion of the automated winder illustrated in FIG. 18A showing the winder arm below the loading stick or receiving member.

FIG. 18C is a schematic illustration of a portion of the automated winder illustrated in FIG. 17C showing the winder arm at a first position with respect to the loading stick or receiving member.

FIG. 18D is a schematic illustration of a portion of the automated winder illustrated in FIG. 18C showing the winder arm at a second position with respect to the loading stick or receiving member.

FIG. 19 is a partial perspective view of a portion of the winder arm of the winder of FIG. 17A with the winding mechanism attached above the winder arm according to embodiments of the present invention.

FIG. 20A is a top perspective view of a portion of a winder arm illustrating an enclosed chute or channel according to embodiments of the present invention.

FIG. 20B is an end view of the winder arm shown in FIG. 20A.

FIG. 21 is a side view of an automated winder system illustrating the winder attached below the winding arm according to embodiments of the present invention.

FIG. 22 is an end view of the winding mechanism shown in FIG. 21.

FIG. 23 is an end view of the winder arm shown in FIG. 21.

FIG. 24A is a perspective view of an alternative embodiment of an automated winder according to the present invention.

FIG. 24B is a side perspective view of the device shown in FIG. 24A.

FIG. 24C is a front view of the device shown in FIG. 24A.

FIG. 24D is a side perspective view of a portion of a winder according to other embodiments of the present invention.

FIG. 24E is side view of the winder shown in FIG. 24D.

FIG. 24F is an enlarged side view of a winding mechanism shown in FIG. 24E.

FIG. 24G is an enlarged side perspective view of a portion of the mechanism shown in FIG. 24F.

FIG. 25A is a side view of a discharge portion of the arm illustrating an end guide according to certain embodiments of the present invention.

FIG. 25B is a side perspective view of an alternate configuration of an end guide according to certain embodiments of the present invention.

FIG. 26A is a schematic of a winding pattern according to embodiments of the present invention.

FIG. 26B is a schematic of another winding pattern according to embodiments of the present invention.

FIGS. 27A–27G are schematic front views of illustrations of exemplary winding patterns that may be used to straddle load, wrap, or position product onto a receiving member according to embodiments of the present invention.

DESCRIPTION OF EMBODIMENTS OF THE INVENTION

The present invention will now be described more fully hereinafter with reference to the accompanying figures, in which embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Like numbers refer to like elements throughout. In the figures, certain layers, components or features may be exaggerated for clarity, and broken lines illustrate optional features or operations unless specified otherwise. The sequence of operations (or steps) is not limited to the order presented in the claims unless specifically indicated otherwise. Where used, the terms “attached”, “connected”, “contacting”, and the like, can mean directly or indirectly, unless stated otherwise.

In the description of the present invention that follows, certain terms are employed to refer to the positional relationship of certain structures relative to other structures. As used herein, the term “forward” and derivatives thereof refer to the general or primary direction that food travels as it moves inside a food processor from a processing point or region to the next processing point or region; this term is intended to be synonymous with the term “downstream,” which is often used in manufacturing environments to indicate that certain material being acted upon is farther along in the manufacturing process than other material. Conversely, the terms “rearward” and “upstream” and

derivatives thereof refer to the directions opposite, respectively, the forward and downstream directions.

The automated apparatus, systems and methods of the present invention may be particularly suitable to provide a substantially continuous supply of empty food support members such as rods for automated loading with elongated food items. When "loaded," the support members or rods can support multiple draped lengths of food as the food is transported downstream onto a trolley, car, track, or the next desired workstation and/or for storage or in an in-process queue. As used herein, the terms "support member" or "transfer support member" are used interchangeably with the term "carrier member." The support member **40** (FIG. 2A) may be elongated and can have any suitable configuration with a length sufficient to hold the desired amount of product thereon. Examples of elongated support members include, but are not limited to, bars, rods, or vertically spaced connected or independent pairs of bars or rods. The support member may be a substantially straight elongated rod or bar having a circular cross-section with a non-disrupted or continuous outer perimeter surface or may be otherwise configured as will be discussed further below. However, it will be appreciated by those of skill in the art that the present invention encompasses a number of different configurations that can act as suitable support members and the present invention is not limited to the embodiments described herein. In addition, in operation, a plurality of elongated support members, of the same or different configurations, may be sequentially serially loaded and removed from the automated positioning apparatus. The product may be loaded in substantially even lengths of loops or in uneven lengths of loops, or combinations thereof, over each or particular ones of the support members.

Examples of elongated food items include, but are not limited to, elastic or partially elastic food items such as cheese (e.g., mozzarella strands), dough (for incubation), pasta, meat sticks or strands, licorice or other strands of candy, and meat products. Of course, the processing system can be configured to wind or transfer other items. For example, other elongated products include candles, ropes, cables, wires, hose, tubing, and the like.

In certain embodiments, the present invention is used to transfer and load a length of an elongated extruded product held in a casing onto a support member. The casing can be any suitable casing (edible or inedible, natural or synthetic) such as, but not limited to, collagen, cellulose, plastic, elastomeric or polymeric casing. The elongated product can be an elongated meat product. Exemplary meat products include, but are not limited to, strands of meat (that may comprise pepperoni, poultry, and/or beef or other desired meat), processed meat products such as strand(s) or continuous lengths of meat sticks (including whole or partial meat mixtures), sausages, hotdogs, and the like. The term "continuous" is used interchangeably with "contiguous" to mean that the product is connected or joined (directly or indirectly) over its length.

The elongated product can be configured as a continuous length of product having a length of at least about 20–25 feet per strand, and typically at least about 50 feet. In other embodiments, the length continuous product may be up to about 150–200 feet, or even longer. The elongated product may be segmented or non-segmented, i.e., a length of chain-like linked items, or a strand or multi-stranded length of non-chain linked product. Other embodiments may load the elongated product in a series of non-looped discrete

lengths. The discrete lengths may be any desired length or combinations of lengths, such as, but not limited to, lengths between about 1–20 feet.

The elongated food item may be elastic (at least in tension) so as to allow some stretching without unduly altering or deforming its desired shape and/or cross-section during processing. The elongated food item may be an extruded product that is held in a natural or synthetic casing as noted above. Other embodiments contemplate product that have rigid configurations but are movable link to link, such as chains of material having sufficient rigidity to retain its shape during processing and/or use (formed of a solid or composite metal, polymer, and/or plastic and the like).

In operation, in certain embodiments, the elongated product may have an exterior surface that, during the loading process, exhibits increased friction relative to a finished, cured, or dried configuration. For example, a processed meat mixture that is held in a collagen casing, prior to finishing, can be described as having a relatively gelatinous, sticky external residue that can cause the food to attempt to stick to a support surface.

Turning now to FIG. 2A, one embodiment of an apparatus **30** for automatically providing, presenting, and/or positioning carrier members **40** for loading is shown. The apparatus **30** is configured to hold and move serially, a plurality of spaced-part carrier members **40** along a desired travel path **50** that is defined by a travel track **30t** associated with the platform or carousel of the apparatus **30p** which the members **40** follow. As shown, the automated apparatus **30** can be configured such that a portion is adjacent a product loading zone **20z** that discharges elongated continuous lengths of product **25** therefrom. The apparatus **30** can be configured to serially automatically present (align and/or position) the carrier or support members **40** such that they are in cooperating communication with the loading equipment in the loading zone **20z**.

The apparatus **30** includes a plurality of mounting brackets **30b** that are operatively associated with the track **30t**. The mounting brackets **30b** are held in spaced apart intervals or locations about the track **30t** or perimeter of the apparatus **30** and are configured to receive and releasably secure the end portion **40a** of the carrier or support member therein.

The mounting brackets **30b** can hold the end portion **40a** in a manner that allows the member **40** to pivot about a pivot joint **30p**. The mounting brackets **30b** are operatively associated with the track **30t** that advances and moves the mounting brackets **30b**, which, in turn, move the respective elongated carrier support members **40**, about the travel path **50**. The mounting brackets **30b** may be outwardly extending to allow for ease of alignment during loading. In other embodiments, the mounting brackets **30b** may be flush with the track or mounted inwardly of the apparatus (not shown).

The track **30t** of the apparatus **30** may be endless and/or curvilinear as shown in FIG. 3. As is also shown in FIG. 3, the carrier members **40** can be elongated and may be configured to travel only a portion (typically a major portion) of the length of the track **30t**. In the embodiment shown, empty support members **40** can be introduced individually at a first location "A" disposed upstream of a loading zone **20z** and the loaded or filled support member **40** can be removed at second location "C", located downstream of the loading zone **20z**. As such, the brackets **30b** may travel without support members for a minor portion of the track **30t**. Other track and path configurations may be employed and a common location or a plurality of entry/exit locations maybe used so that the elongated members **40** travel the entire or a subset of the length of the track **30t** (not shown).

As noted above, a first end portion **40a** of the carrier members **40** can be pivotably attached to the apparatus **30** so that each is able to independently move with respect thereto. In operation, as shown in FIG. 3, this mounting configuration allows the second end portion **40b** of the members to retract toward or extend away from the track **30t** (toward and/or away from the carousel body or platform **30p** of the apparatus) during operation.

The track **30t** may be operatively associated with an advancement or drive system that moves the brackets **30b** forward along the track or desired travel path. As such, the advancement system can comprise one or a series of conveyors, belts, cables, or chains, gearing, cams, or mechanical, electrical, pneumatic, hydraulic powered mechanisms, linkage assemblies, or combinations of same, as well as other suitable drive means and/or transport mechanisms.

In certain embodiments, the carrier or support members **40** travel substantially continuously at a substantially constant speed along a major portion, or all, of the travel path **50**. In other embodiments, the members **40** may operate at a variable speed, or intermittently slow or halt to interrupt forward movement so as to allow the support members **40** and/or brackets **30b** to dwell at a particular location for a desired amount of time.

FIG. 3 also illustrates that the carrier member **40** can move from a first location "A" where it has a first orientation such that the elongated support member **40** is held substantially orthogonal to the direction of travel associated with the predetermined travel track **30t** to a second location "B" with a different orientation. At location "B", as shown, the elongated support member **40** is held substantially parallel to the direction of travel associated with the predetermined travel track **30t**. At location "C", the member **40** may be again rotated to be substantially orthogonal to the direction of travel associated with the travel track **30t**. Location A may be associated with a new or "empty" member loading or supply station **120** (represented by the insertion arrow **120i**), and location C may be associated with a loaded or "full" member removing station **121** (represented by the detachment arrow **121d**). As such, the (elongated) carrier members **40** are individually releasably mounted to mounting brackets **30b** spaced apart a distance so as to define the spacing between adjacent members **40** during operation. In use, "fresh" sanitized/sterilized support members **40** are individually introduced at one or more locations (shown as a single location A), and individually removed at one or more locations (shown as a single location B) after the members **40** are loaded.

In other embodiments, the carrier members **40** can be configured to permanently mount to the track **30t** and/or carousel **30** so as to repeatedly travel the circuit. In this embodiment, the food can be unloaded at a desired unloading station or stations, manually or automatically. "Permanently" as used herein means that the members **40** may be used repetitively during a production shift, remaining mounted, without requiring removal from the device **30**. However, selected ones or all members **40** may be removed for periodic repair or cleaning as desired.

As shown in FIGS. 2A and 3, the loaded members **40** may be interconnected with intermediate lengths of product **25i** strung between adjacent ones of the elongated support members **40**. In such embodiments, as shown in FIG. 3, it may be desirable to cut the product along the intermediate segment **25i**. FIG. 3 illustrates that such cutting may be carried out automatically with a cutting implement **75** configured to advance and cut the product **25** at desired time

intervals set to correspond to the speed of the elongated members **40** so that adjacent members are detached and/or unconnected.

FIG. 2A illustrates that, in position in the loading zone **20z**, the member **40** is located in cooperating alignment with the loader that discharges the product onto the support member. As shown, the loading zone comprises a suitably located winder arm **20**. However, other loader, discharge configurations, mechanisms, and devices may also be used to supply the product desired to be loaded.

As shown, the member **40** extends within the perimeter of the travel path **20p** defined by the translating winder arm **20**. In certain embodiments, the support member **40** can be located so that it is centrally located within the boundary of the movement of the arm **20** during the loading operation. In other embodiments, the carrier member **40** can be asymmetrically positioned (such as closer to the top, bottom or one side of the winder arm **20**). The direction of travel of the arm **20** is shown as counterclockwise in FIG. 2A, but may be configured to be clockwise as well. The support member **40** may be configured to travel proximate the loading zone **20z** and downstream thereof in a unidirectional manner as the winder arm **20** translates to distribute multiple loops of product along a desired length of the support member **40**. The timing, movement pattern, and product release rate, can be coordinated with the spacing of the support members **40** and the speed of movement of the support member **40** in the apparatus **30** to substantially continuously feed serially presented empty support members into the loading zone **20z** after an immediately forward one is full and departs the loading zone **20z**.

As shown by the arrow in FIG. 2A and FIGS. 27F–27G, the winder arm **20** can move in a predetermined directional pattern **20p** which is a closed path including two different axis of travel, typically including both X and Y axis directional components. The closed path may be shaped in any desired suitable configuration, including, but not limited to, oval, teardrop, circular, elliptical, hourglass, square, or rectangular, so that, in operation, it causes the elongate product to wrap to the desired configuration. FIGS. 2B and 27A–27E illustrates that the winder arm **20** may be configured to move in a transverse (open or closed) pattern **20p** so as to serially load or drape over the member **40** discrete lengths of non-looped elongated suspended lengths of product along the support member **40**.

The elongated continuous or discrete length of product may be loaded so that it has substantially uniform suspended lengths along the member **40** as shown in FIGS. 2A, 2B, 17A, 17C, 17E or may be loaded to provide non-uniform suspended lengths of product **25** (FIGS. 13A, 13B).

The winder arm **20** may be programmably configured to alter its winding pattern, winding speed, and the like, depending on the product being processed. In any event, the winder arm **20** is configured to move a sufficient distance above and below the support member **40** so as to load or loop the elongate product **25** thereon.

In certain embodiments, the upstream processing station that feeds the loading station **20z** winder arm **20** can be the extruder **10** (such as the conventional extruders/stuffers as shown in FIGS. 1A–1C) and the upstream portion of the winder arm **20** can be positioned proximate to, and in cooperating alignment with, a discharge port **10p** of the extruder (or stuffer) **10** or intermediately positioned member such as a chute.

In operation, as shown in FIGS. 2A, 2B the support member **40** can be aligned with the winder arm **20** at a first position that is toward the upstream end of the arm **20** and

during loading can be gradually translated (typically unidirectionally) to be closer to the downstream end of the arm **20** all at substantially the same height so that the support members **40** are held in a substantially level manner during and after loading. Moving the support member **40** during the loading operation can distribute multiple strands, bights, or loops of product over the desired length of the member **40**.

In certain embodiments, the support member **40** moves at a substantially constant speed along the track **30t** that may be synchronized and/or responsive to one or more of the speed of the winding (speed of the arm), the speed of forward movement of the product **25** as it exits the arm **20**, and the desired looping arrangement/configuration (length of the loops or suspended lengths) on the member **40**.

The length of the winder arm **20** can vary depending on various factors, such as, but not limited to, the size of the product, the forward speed of the product, the desired winding pattern and the like. In certain embodiments, the length of the arm **20** is sized to be at least the length of the transport member **40**. In other embodiments, the length of the support member is at least about 2 feet, and typically at least about 3 feet. In certain embodiments, the support member **40** can be about six feet long.

Various automated detectors can be placed at desired locations along the apparatus **30** and/or winder arm **20** to verify proper operation and to render an alert when an abnormality is indicated. Examples of such detectors include optical detectors (infrared or otherwise that respond to changes in visual intensity or generated light beams), flow meters, pressure meters, temperature sensors, and the like.

In certain embodiments, the speed of the track **30t** and/or support members **40** held and advanced by the apparatus **30** may be between about 2–10 ft/min, and in particular embodiments, at about 4–6 ft/min.

FIGS. 4–9 illustrate a sequence of operations following a single support member **40** through an exemplary travel path provided by the positioning apparatus **30**. FIG. 4 illustrates the initial loading or supplying of a (empty) support member **40** onto the apparatus **30** at the supply station **120**. In this embodiment, the support member **40** is loaded into the bracket **30b** at an introduction location (shown as position A) in an orientation that is different from its upstream orientation. As shown by the curvilinear arrow, the track **30t** continues to move the receiving bracket **30b** forward during the supply step, automatically bringing the next adjacent bracket **30b** forward to repeat the loading process.

FIG. 5 illustrates that after or during insertion (proximate, and typically, downstream of location A) into the bracket **30b**, the support member **40** can be reoriented and aligned so that the outer portion **40b** of the support member **40** can be rotated inwardly. In the embodiment shown, the support member **40** pivots so that it is disposed substantially parallel to and evenly spaced with respect to the track **30t** or apparatus **30** along the length of the support member **40**. At full operational capacity, the apparatus **30** positions the support members **40** so that each is spaced apart but adjacent the support members **40** that are positioned immediately forward and rearward thereof about a major portion of the track **30t** as shown in FIG. 3.

FIG. 10A illustrates that the support members **40** may be held by the apparatus **30** such that when viewed from the top, they present an angular orientation relative to the carousel **30**, so that the first portion **40a** is held closer to the track **30t** than the second portion **40b**. As shown in FIG. 10A, as viewed from the top, the support members **40** can be held during a portion of travel along the travel path at an obtuse angular orientation “ α ” that is greater than 90

degrees, typically from about 120–160 degrees, from the axis defined by an axis line (shown in broken line) extending through the bracket arm **30a** and associated pivot joint. In other embodiments, the support members **40** may be held to be in substantially straight alignment throughout a major portion of the travel circuit. As shown in FIG. 10B, the support members **40** may be mounted on the carousel while in other embodiments the support members may be oriented to taper inwardly relative to the travel direction (not shown).

In certain embodiments, as shown in FIGS. 2A and 2B, the support member **40** is held in the apparatus or platform so that it has a free length that can be readily accessed for loading (such as aligned and positioned) at the loading zone **20z**. As also shown in FIGS. 2A, 2B, and 4–9, one end portion **40b** can be configured to remain free during its travel along the travel path or track **30t**. In other embodiments, both end portions **40a**, **40b** of the members **40** may be held against the carousel **30** (such as via a double bracket holding arrangement) (not shown). The end portion that is held may be the end or an inward portion of the member **40**. In other embodiments, one or more mounting locations may be used as well as an intermediately positioned (between the opposing end portions) mounting location may be used.

In other embodiments, as shown in FIG. 10B, a first end portion **40a** of a support member **40** can be mounted in the bracket **30b** with a second end portion **40b** held in a secondary bracket **30s** that may be disposed on a different adjacent primary bracket **30b** (or on the track as a secondary bracket (not shown)) spaced from the first bracket **30b**. As shown in FIG. 10B, a first end portion **40a** of the support member can be held in the first bracket **30b** and the second end portion **40b** can be held on a rear bracket **30s** that may be mounted to a bracket **30b** located downstream of the bracket **30b** holding the first end portion **40a** of the support member. FIG. 10C is a side view that illustrates the secondary bracket **30s** incorporated into the holding bracket **30b**.

FIG. 10B also illustrates another example of a holding configuration and orientation for the support members **40** along the travel path. As shown, the support members **40** have a length and are in spaced apart relationship so that the rearward portion **40b** of an upstream member **40** extends proximate to or beyond the corresponding adjacent downstream bracket **30b**. In the orientation shown, the support member **40** tapers outwardly slightly from front to back, so that the rearward most portion of a forward member **40b** resides proximate to but outwardly of the boundary of the front-end portion **40a** of the adjacently located downstream or rearwardly positioned support member **40**.

The support members **40** may be manually or automatically turned to a desired orientation or orientations along the travel path. In certain embodiments, a guide mechanism (not shown) can be disposed downstream of the introduction location A (FIG. 4) that deflects the support member **40** to a desired orientation. In other embodiments, the bracket **30b** can be configured with a cam, linkage, or other internally mounted mechanism (not shown) that is operated to cause the support member **40** to turn to a predetermined orientation(s) as it travels along the track **30t**.

FIG. 6 illustrates, in broken line, a series of orientations that the support member **40** moves through as it travels in the arcuate region of the travel path to be aligned and positioned in cooperating relationship with the loading zone **20z**. It is noted that where the apparatus **30** has only linear tracks, such a pattern will not be required (not shown).

FIG. 7 illustrates that in certain embodiments, as the member **40** progresses forward at and/or away from the loading zone **20z**, the member **40** can travel in unidirection-

15

ally. As shown, the member **40**, during and after loading with product **25**, can be held and moved so that it has a straight travel pattern with the member **40** held level (substantially horizontally to keep the strands, bights, loops or other straddled arrangement of product distributed along a major portion of the length of the member) and parallel to the travel track **30t**.

FIG. **8** illustrates that the intermediate length of product extending between two adjacent support members **40** downstream of the loading zone **20z** can be parted or split. The parting can be automatically or manually performed while the adjacent support members **40** are moving, typically without disrupting the normal speed and/or continuous flow of product/support members **40** along the track **30t**. The bracket **30b** may include an outer surface configuration **30s** that provides a solid cutting surface that is sufficient to receive the sharp edge contact of a cutting implement and/or the associated cutting force over a suitable component life. Other cutting means can also be used, including, but not limited to, lasers, ultrasonic devices, water jets, and the like.

FIG. **9** illustrates that the support member **40** loaded with product **25** can be detached from the apparatus **30** at removal location "C". The detachment can be performed while the support member **40** is held at a desired removal orientation. As shown, the support member **40** is moved so that the second end portion **40b** extends outwardly from the body of the apparatus **30** which may provide easier removal and/or external access to the loaded member **40**.

Although illustrated as having particular loading and supply member introduction and removal locations, it is noted that other locations can be selected. For example, a plurality of different introduction locations can be used, so that a particular location loads every other bracket that passes thereby. Similarly, a plurality of different removal locations can be selectively used. In other embodiments, the supply members are mounted to travel repeatedly along the circuit to allow a number of loading operations thereon and hence, remain in position during the removal (with no single introduction or loading location needed). At a desired time, the food can be lifted, scooped, or otherwise removed from the support members **40** (at one or more desired locations). It is also noted that the support member **40**, although shown as being introduced at a 90-degree orientation in certain of the figures such as FIG. **4**, may employ other desirable entry or loading orientations. In addition, the support members **40** need not move into parallel alignment to the platform **30** as they travel along the track **30t**. Instead they may be loaded into this orientation and remain this configuration along a major portion of the travel path or travel in alternative orientations.

In certain embodiments, two loading stations can be positioned and opposing ends of the apparatus (not shown). In these embodiments, the apparatus **30** can be configured with a sufficient length and/or configuration to include two different sets of introduction, loading, and removal locations, potentially increasing the loading capacity.

It is also noted that, in certain embodiments, as shown in FIG. **11A**, the apparatus **30'** may be configured with a corresponding pair of dual brackets **30b₁**, **30b₂** at each, or selected ones, of the support member mounting positions. As such, the apparatus **30'** can be configured to receive a pair of independent overlying aligned elongated support members **40** that are held in the apparatus **30'** to be vertically spaced apart and concurrently moved to be simultaneously loaded with product. In this embodiment, the winder arm **20** moves a distance in its winding pattern that is sufficient to envelope and/or move around the perimeter defined by the two spaced

16

apart rods, the upper one suspending the product **25** and the lower one helping to provide a lower dimension for the looped product. FIG. **11B** illustrates that a pair of support members **40₁**, **40₂**, may be held in a single bracket **30b** that defines the alignment orientation and pivotability of the members **40**.

FIGS. **11C–11E** illustrate examples of alternate embodiments of support members **40**. As shown in FIG. **11C**, the support member **40'** may be configured as a pair of rods **40r₁**, **40r₂** that may be attached. FIG. **11D** illustrates that the support member **40''** may be configured with a continuous sheet of material, the upper portion may have additional width and/or at least one end portion (shown as two) that allows for insertion into the bracket **30b**. The body of the support members may be solid, perforated, foraminated, or include one or a plurality of apertures or be otherwise configured to reduce weight and/or promote airflow there-through. Similarly, the member **40** may include one or more handles or other externally accessible handling means disposed along the length and/or at selected end portions thereof to promote ease of handling to transport the loaded member to a trolley or another active station (not shown). In addition, in operation, a plurality of support members, of the same or different configurations, may be sequentially (manually or automated) serially loaded and removed by aligning them with the winder **20**.

Examples of other configurations of support members **40** are shown in FIGS. **12A–12E**. These examples are non-limiting to the contemplated scope of the invention as there are many suitable support member configurations as will be appreciated by those of skill in the art. FIG. **12A** illustrates that the support member **40** may be configured as a planar bar. FIG. **12B** illustrates a support member **40** configured as a rod with a semi-circular cross-sectional profile. FIG. **12A** illustrates that the support member **40** may include a protrusion **40pr** that is configured to mate with the bracket **30b** to help releasably secure the support member **40** to the apparatus **30**. Similarly, FIG. **12D** illustrates that, at least one end portion **40b** of the support member may be configured with a plurality of outwardly extending protrusions to releasably engage with the bracket **30b**. FIG. **12D** also illustrates that at least one end portion of the support member **40b** may include an aperture **40a** that may be used to help secure the support member **40** to the bracket **30b** and/or to reduce the weight thereof. FIG. **12E** illustrates that at least one end portion **40b** of the support member may include a recess that can lock in position to releasably secure it to the apparatus **30**.

FIGS. **14A–14F** illustrate a sequence of operations that can be carried out to arrange suspended elongated product on the carrier member **40** according to embodiments of the present invention. As shown in FIG. **14A**, a packing mechanism **175** is cooperably aligned with a carrier member **40** that is, in turn, cooperably aligned with an automated winder **20**. The automated winder **20** includes a winding arm **21** and has an associated winding or motion pattern **21p** that discharges and loads suspended elongated product onto a cooperably aligned carrier member **40** and is discussed in more detail below. The carrier member **40** can be loaded with at least one length of elongated product **25**. As shown, the product straddles onto the carrier member **40** so that the product defines suspension regions **121S₁–121S_n**. The straddling can be carried out in different manners to load, suspend, hang, or drape the product **25** onto the carrier member **40**. For example, as shown in FIG. **16**, the straddling is performed so that the product **25** is arranged in a plurality of loops on the carrier member **40**. FIG. **17C**

illustrates that the straddling configuration can be a continuous length of non-looped bights $B_1, B_2 \dots B_n$ having a series of curves while FIG. 17E shows discrete lengths of products hanging from the carrier member 40.

In any event, the packing mechanism 175 includes an elongated packing arm 175a that moves through a repeating motion cycle illustrated by the arrows proximate the packing arm 175a in FIGS. 14A–14F. The packing arm 175a includes opposing first and second end portions 175a₁, 175a₂, respectively. The first end portion 175a₁, can be formed as or include a fork member 176 that, in operation, periodically reaches over and down to contact the outer surface of the carrier member 40 (FIGS. 15A, 15B) and/or a portion of a suspended elongated product 25 held on a carrier member 40 to swipe, move, push, or pull regions of the product 25 in a desired direction on the carrier member 40 to provide a more closely spaced or symmetrical or desired loading/packing arrangement.

As shown in FIGS. 14A–14F, the packing mechanism 175 also includes a drive mechanism 177 attached to the second end portion of the packing arm 175a₂ to repeatedly move the packing arm 175a through a predetermined motion cycle so that the fork member 176 serially moves through its travel cycle. The drive mechanism may be automatically or manually operated. FIG. 14A illustrates that the drive mechanism 177 can be operably associated with an automated drive means such as a motor 177m. As shown by the sequence in FIGS. 14A–14F, the cycle sequence may be such that the fork member 176 moves in a first longitudinal direction (shown in the rearward substantially longitudinal direction in FIG. 14A), travels down a desired vertical distance sufficient to cause the fork member 176 to engage the carrier member 50 (FIGS. 14B, 14C and 15A, 15B), moves in a second longitudinal direction opposite the first longitudinal direction with the fork member substantially horizontal (FIGS. 14D, 14E), then rises a distance to reside above the carrier member 40 (FIG. 14F). The arm 175a and the fork member 176 may be configured to stall for a desired interval of time during a portion of the cycle, typically after they rise (FIG. 14F) and before they descend again (FIG. 14B). The stall or static interval can be timed to define when the fork member 176 will next contact the carrier member 40. The stall interval can depend on the discharge speed of the product 25 from the winder mechanism 20, the speed of the winder 20 as it moves through its winding path 21p and the number of times it is desired for the fork member 176 to contact the carrier member 40 and/or product 25. For example, in certain embodiments, the winding arm 21a may be configured to operate with a pause of about 0.5–2 seconds at one or more locations in its travel path, as the winding arm 21a (FIG. 17A) moves about the carrier member 40. In other embodiments, increased stall times can be used, while in still other embodiments no stall time is used as the amount or speed of drag or movement of the fork member 176 can be timed to continuously move through its operative positions in a variable or constant speed. Combinations of variable speeds, constant speeds, and the use of stall intervals may also be used depending on the application.

For example, the carrier member 40 can be loaded by having the winding arm 21a present the product onto the carrier member 40 so that it is straddled in a desired suspended configuration. The straddling operation has an associated speed that is dependent upon the discharge rate of the product 25 from the winder 20 and the speed of movement of the winder arm 21a about the carrier member 50. Similarly, the packing arm 175a also has an associated speed. The packing arm 175a speed can be adjusted based on

the speed of the straddling operation so that it does not disrupt the loading and can move the product 25 at desired intervals during the loading cycle.

In operation, in certain embodiments, the straddling operation is carried out by the winding arm 21a as it travels in a predetermined pattern and discharges food 25 therefrom in a forward direction while the winding arm 21a is traveling through its pattern 21p. The packing arm 175a can be configured to move rearward and forward in a repetitive packing cycle. That is, the repetitive packing cycle can be performed so that the packing arm 175a serially moves in a rearward direction above the carrier member 40 relative to the direction of the discharged food, then stops for a static interval before it declines to contact the carrier member 40 and moves forward thereby pushing the suspended region in back 176b of the packing arm 175a forward, and then rises to complete a packing cycle.

In certain embodiments, the carrier member 40 can be translated forward during the operation of the packing mechanism 175. In this situation, the fork member 176 can sequentially engage different segments of the product and/or different locations of the carrier member 40 to thereby arrange different portions of the product to be closer together. The carrier member 40 is shown as moving forward (horizontal arrows proximate the carrier member 40 in FIGS. 14B–14F) with the packing arm 175a also moving or pushing the suspended product forward on the carrier member 40 itself. However, the movement of the arm of the mechanism 175a and translation of the carrier member 40 can be reversed. In addition, in lieu of moving the carrier member 40, the winding arm 21 of the winder 20 and the packing mechanism 175 can be moved with the packing mechanism being stationary to distribute elongated product over a desired length of the carrier member 40.

Further, in certain embodiments, instead of positioning the packing mechanism 175 in front of (downstream of) the winding arm 21 as shown, the packing mechanism 175 may be placed to the side or rear of the winding arm 21 and be configured to reach in and periodically push, pull or move the suspended product forward or rearward on the carrier member 40 (not shown).

FIGS. 14A and 14B illustrate that the winding mechanism 177 can be mounted to a platform 175p that holds at least a portion of the mechanism 177 thereon. As shown, the platform 175p includes an upper bracket 190 that holds the packing arm 175a in a manner that allows the packing arm 175a to pivot thereon. The platform 175p can also include a lower bracket 191 that can hold an edge portion of the carrier member 40. The lower bracket 191 may be operably associated with a drive track 193 mounted on the platform 175p that automatically positions the carrier member 40 at the packing station and/or moves the carrier member 40 forward at a desired speed during the packing operation.

As shown in FIGS. 14A and 14B, in certain embodiments, the drive mechanism 177 can be a four-bar linkage mechanism that includes a rotatable wheel 178 that can be mounted to the platform 175p. The wheel 178 can be powered to be automatically driven by a shaft connected to a motor as shown schematically in FIG. 14A. The wheel 178 can be substantially continuously operated so as to repeat the packing cycle(s) a plurality of times for each carrier member 40 presented to the packing arm 175a. The wheel 178 is connected to a linkage 179 that may travel in a restrained slot 180 formed in the wheel 178. The linkage 179 is attached to the arm 175a. In operation, as the wheel 178 rotates, the linkage 179 repeatedly follows a defined path (shown by different locations in FIGS. 14A–14E (FIG. 14F

19

shows the position shown in FIG. 14A), and pulls the arm 175a through a desired motion output.

Of course, any suitable mechanisms and/or components can be employed, including, but not limited to, cam/follower arrangements, pistons (pneumatic or hydraulic), combinations of differently configured linkages with any of the above as well as other electromechanical configurations that can generate the desired repeated motion.

The packing arm 175a may be configured to directly contact each suspended region 121S₁ through 121S_n (FIG. 16) or only selected ones of the suspended regions. The packing arm 175a may be operated to move groups of suspended regions in a desired direction on the carrier member 40 or a selected suspended region independently of the others. In certain embodiments, the packing arm 175a repeatedly moves to push serially successive spaced-part suspended regions forward along the carrier member 40. In other embodiments, the packing arm 175a pushes non-serially successive spaced-apart suspended regions forward along the carrier member 40.

The product 25 may be arranged in a looped (FIGS. 16, 17A) or non-looped (FIGS. 17C, 17E) configuration on the carrier member 40 as will be discussed further below. FIG. 16 illustrates that a continuous length of elongated product 25 is suspended with substantially even lengths 251₁, 251₂, 251_n, of product on opposing sides of the carrier member 40 over a desired length of the carrier member 40. Other product loading or draping configurations may also be employed.

FIGS. 15A and 15B illustrate an example of the fork member 176 that is attached to the end portion of the arm 175a. The fork member 176 includes a forward or front surface 176f and a rear surface 176b, and may also include an aperture 176a that is sized and configured to correspond to the width of the carrier member 40. The fork member 176 can be sized so as to rest on the carrier member 40 as it pushes, wipes, and/or moves the product on the carrier member 40. The fork member 176 may directly or indirectly contact the product and/or the carrier member 40. For example, as shown the fork member 176 can snugly abut the carrier member 40 and push the food in the desired direction. The fork member 176 may be formed of stainless steel or other material suitable for processing the product (such as food). Lubricating coatings may be employed to inhibit friction between the fork member 176 and the carrier member 40 and/or product 25. In other embodiments, the fork member 176 may be configured to controllably discharge fluid such as air, water, or other pressure applying means, in a desired orientation to move the product along the carrier member 50 (not shown).

Referring again to FIGS. 15A and 15B, in operation, the fork member 176 travels over the carrier member 40 (FIG. 15A) and then travels down a distance to cooperably engage the carrier member 40 (FIG. 15B) so as to move the product along the carrier member 40 in a desired direction to promote efficient side-by-side abutting placement or closely spaced alignment between adjacent suspended regions 121S₁, 121S₂, 121S_n, as shown in FIG. 16.

Turning now to FIG. 17A, one embodiment of an automated winder 20 is shown. The automated winder 20 includes an elongated arm 21 with first and second opposing end portions 21a, 21b, respectively, and a winding mechanism 130. In this view, the winding mechanism 130 is schematically illustrated by a translation linkage 130L that is attached to the arm 21 in a manner that allows it to repetitively move the arm 21 in a desired translating motion or pattern. At the other end of the translation linkage 130L

20

can be any number of suitable translation generation means as will be appreciated by those of skill in the art. As shown, the arm 21 directs the elongated product 25 onto a desired transport support member 40 (shown as a stick or rod). In operation, a plurality of support members 40 are serially placed in aligned cooperating position with the arm 21 of the winder 20 so that each support member 40 can be successively loaded or wound with looped elongated product 25.

In certain embodiments, the winding mechanism 130 is configured to provide a motion for the arm 21 that includes at least a substantially continuous or repeating motion (open or closed path) as indicated by the solid line arrows positioned proximate the translation linkage 130L. Additionally, the winder mechanism 30 may also be configured to translate in a more complex, multi-directional motion (as indicated by the broken-line arrows shown adjacent the solid-line arrows, the motion may also include movement that is directionally in and out of the paper "the Z axis"). Thus, as shown by the dotted line arrows adjacent the solid line arrows, the translation linkage 130L may drive the arm 21 to move in a direction which is a closed path including two different axis of travel, typically including both X and Y axis directional components. The closed path may be shaped in any desired suitable configuration, including, but not limited to, an oval, teardrop, circular, elliptical, hourglass, square, or rectangle, so as, in operation, it causes the elongate product to wrap to the desired configuration. Further the winding mechanism 130 may be programmably configured to alter its winding pattern, winding speed, and the like, depending on certain parameters such as the product being processed and/or the loading configuration desired.

By way of illustration, as shown in FIG. 17B, the arm 21 can have a maxima position at a first vertical height 21h₁, two intermediate positions at a second lesser height 21h₂ (shown with the arm 21 in dotted line below the maxima height), and a minima position 21h₃ at still a lesser vertical height (shown with arm 21 at yet another lower position at a minima height). The arm 21 is configured to move a sufficient distance above and below the transport member 40 so as to load or loop the elongate product 25 thereon.

FIG. 17B illustrates but one embodiment of a rotational motion pattern 21p for the arm 21 in which the arm 21 successively moves through a selected repeating pattern that may be traveled as an open or closed path pattern. In certain embodiments, as shown in this figure, the pattern 21p may be substantially elliptical or oval. In this pattern, the arm 21 travels through the intermediate positions both as it is moved and/or rotated in the closed path in the downward and upward directions. In position, the transport member 40 is located within the perimeter of the enclosed closed travel path defined by the translating arm 21. In certain embodiments, the transfer member 40 can be located so that it is centrally located within the boundary of the movement of the arm. In other embodiments, the transfer member is asymmetrically positioned (such as closed to the top, bottom or one side of the arm movement). The direction of travel is shown as clockwise in FIG. 17B, but may be configured to be counterclockwise as well.

FIG. 17A shows that the first end portion 21a of the arm is positioned a length away from the discharge port 10p of the upstream processing station. As shown, the upstream processing station can be the extruder 10 (such as the conventional extruders shown in FIGS. 1A-1C) and the second end portion 21b of the arm is positioned proximate to, and in cooperating alignment with, a discharge port 10p of the extruder (or stuffer) 10 or intermediately positioned member such as a chute. That is, the second end portion of

21

the arm **21b** is positioned so as to receive the elongated product **25** from the upstream device and the opposing (first) end portion **21a** is configured to release the elongated product **25** after the product **25** has traveled a desired distance over the length of the arm **21**. Typically, the product **25** will travel a major portion of the length of the arm, and more typically, substantially the entire length of the arm **21** before it is released. The product **25** can be released directly from the first end portion **21a**, or a discharge nozzle or other discharge port can be attached to the arm **21** and used to dispense the product **25** therefrom.

In operation, the transfer member **40** can be configured to start at a first position that is toward the upstream end **21b** of the arm **21** and during loading is gradually retracted or translated to be closer to the downstream end **21a** of the arm **21** all at substantially the same vertical height (as shown by the horizontal arrows adjacent the transport member **40** in FIG. **17A**). This motion distributes looped product over the desired length of the transport member **40**. FIGS. **18A** and **18B** illustrate the winding translation of the arm **21** with respect to the transport member **40**. The transport member **40** is located at a first position P_1 and is gradually moved forward to a second position P_2 as the arm **21** winds the product **25** thereon. Thus, the transport member **40** moves a distance ΔP .

In certain embodiments, the transport member **40** moves at a substantially constant speed or increments of travel distance that is synchronized and/or responsive to one or more of the speed of the winding (speed of the arm), the speed of forward movement of the product **25** as it exits the arm **21**, and the desired looping arrangement/configuration (length of the loops) on the transport member **40**. In certain embodiments, the movement of the transport member **40**, the winding speed of the arm **21**, and/or the speed of the elongate product **25** as it moves off the arm, can vary to provide variable loading density or looping lengths. Thus, the movement distance and speed of movement of the transport member **40** can vary depending on the desired loading of the transport member and winding speed and loop configuration (length, etc.). Typically, the transport member **40** moves a distance that corresponds to a substantial portion of its length (i.e., greater than about 51–75% thereof). Although described as starting from a rearward position and moving forward, the transport member **40** can be configured to move in the reverse direction also.

FIG. **17C** illustrates an alternate loading arrangement of the elongated product on the transport or receiving member **40** with an example of an associated winding pattern **21p** of the arm **21**. As shown, the arm **21** is configured to load the product in a suspended straddled, non-looped configuration (i.e., the product does not double over or loop to cross or close upon itself). As shown in FIG. **17C**, one or more one continuous lengths of released elongated product can be loaded onto the transfer support member **40** in response to the release of the product **25** from the moving arm during the translation thereof so that the elongated product **25** is arranged in a straddled configuration with a plurality of adjacently arranged non-looped vertical lengths, such as L_2 , L_4 or L_5 , L_7 , hanging on the same side of the transfer support member and a plurality of different adjacent non-looped lengths, such as L_1 , L_2 or L_4 , L_5 , hanging on the opposing side of the transfer support member so that the elongated product **25** has a plurality of suspension contact points $121S_n$ spaced apart about a desired length of the transfer support member **40**. As used herein, the term “suspension contact points” means the discrete physical contact spaces, areas, or regions between the product **25** and the transfer

22

support member **40**. The area or size of the contact points may vary depending on the size, weight, and/or width of the product, and/or the size and/or width of the transfer support member **40**.

Still referring to FIG. **17C**, as shown, the winding mechanism **130** is configured to configure the suspended straddled arrangement of the elongated product **25** on the transfer support member **40** such that, in serial order, a first continuous length of product is arranged so that a first vertical length L_1 of the elongated product extends about one side of the transfer support member **40**, a second vertical length L_2 extends over the opposing second side of the transfer support member **40** after the first length L_1 , a first suspension portion $121S_1$ is located intermediate the first and second lengths L_1 , L_2 , respectively. A third adjacent length L_3 laterally extends along the second side of the transfer support member **40** after the second length L_2 , a fourth vertical adjacent length L_4 extends along the second side of the transfer support member **40** after the third length L_3 , a fifth vertical adjacent length L_5 extends along the first side of the transfer support member **40** after the fourth length L_4 , a second suspension portion $121S_2$ is located intermediate the fourth and fifth lengths L_4 , L_5 , respectively, and a sixth adjacent length L_6 laterally extends along the first side of the transfer support member **40** after the fifth length L_5 .

In operation the arm **21** can move have lateral directional travel components so as to move back and forth across above the transfer support member **40**. In so doing, the elongated product **25** can be discharged to hang or drape from a first side of the transfer support member **40**, cross over the width of the body of the member **40** and hang or drape another vertical segment down the other opposing second side. The arm **21** continues to release the elongated product so that another vertical segment or portion hangs or drapes still on the same second side before it re-crosses over the transfer support member **40** and drapes another vertical length back on the first side of the transfer support member. The non-looped straddled product can be arranged so that the suspended vertical draped lengths are substantially the same, dissimilar, or combinations thereof. The draping motion can be continued so as to substantially fill a major portion or substantially all of the length of the transfer support member with the elongated product **25**. The lateral lengths of product (i.e., L_3 , L_6) can be disposed so that they are substantially horizontal as shown, or in other desired configurations. The length of the lateral segments can alter and can be controlled by the movement pattern and speed of discharge, the speed of the motion of the arm, and the movement and speed of the transfer support member **40** during the loading process or operation.

FIG. **17E** illustrates that in lieu of a single continuous length of product **25**, a plurality of discrete product lengths can be straddle loaded onto the transfer support member **40**. In operation, the winding mechanism **130** causes the arm **21** to release a plurality of discrete lengths of elongated item **25** so that the items are arranged in a suspended laterally spaced apart straddled configuration, each discrete length having opposing first and second end portions $25p_1$, $25p_2$ and an intermediate portion $121S_1$, $121S_2$, therebetween, respectively. In position, the first and second end portions $25p_1$, $25p_2$, respectively, vertically extend to reside adjacent to each other on opposing sides of the transfer support member **40** and the respective intermediate portion $121S_1$ or $121S_2$, defines a respective one suspension contact region that contacts the transfer support member **40**.

Referring to FIG. **17C**, stated differently, certain embodiments of the suspended straddle configuration of elongated

23

product 25 on the transfer support or carrier member 40 is provided so that sections of the elongated product form bights $B_1, B_2 \dots B_n$ that are draped from the rod, with longitudinally consecutive or serially positioned bights, being formed and/or located on opposing sides of the carrier member. The bights are sections of the elongated product that bend or curve but do not intersect. As such, the elongated product has adjacent or serially consecutive bights, each of which can have a series of bends or curves (i.e., defined by serially consecutive vertical, longitudinal, and vertical segments) that are draped on one side of the carrier member 40 before the next bight starts across the other side of the carrier member 40. The loaded transfer member 40 can define a loaded carrier member assembly with elongated product thereon. The product can be arranged on the carrier member so that the elongate product is suspended in a straddled configuration, draped from the carrier member, so that sections of the elongated product form bights, with serially consecutive bights being formed on opposite sides of the carrier member. Each or selected bights can have a plurality of bends or curves and the adjacent bights do not intersect or crossover each other.

FIG. 17D illustrates an exemplary loading motion 21p of the arm 21 that can be used to provide the straddle arrangement shown in either FIG. 17C or 17E. As shown, the loading motion is an open path that has a boundary that has lateral components that permits the arm 21 to travel back and forth across the width of the transfer support member 40. As shown, the arm 21 is disposed so that the travel path boundary primarily extends above the underlying transfer support member 40. FIG. 17D also shows that the travel motion 21p can be substantially arcuate with the shape defined by lowermost points 21p₁, 21p₃, and the maxima position 21p₂. In operation, the arm 21 can repetitively travel in the motion pattern shown 21p or in other suitable motion patterns. FIGS. 27A–27G illustrate exemplary straddle loading motion patterns 21p, some of which are open and some of which are closed travel paths.

FIGS. 27A, 27C, 27D, and 27E illustrate different open arcuate patterns 21p. FIG. 27A illustrates that the arcuate pattern 21p can be reversed so that it turns upward with opposing end portions 21p₁, 21p₂, that are above the transfer support member 40 and a minima location 21m disposed therebetween. FIGS. 27G and 27F illustrate closed path motion patterns 21p for the arm 21. The pattern 21p shown in FIG. 27G is above the rod and has increased vertical travel distance relative to the amount of lateral travel distance. FIG. 27F illustrates that the path 21p may have increased horizontal or lateral travel distance relative to the amount of vertical travel distance. FIG. 27F illustrates that in certain embodiments, no matter whether an open or closed path, and notwithstanding the configuration thereof, the travel motion pattern 21p can be offset, inclined about, and/or not centered on or over the transfer support member 40.

FIGS. 18C and 18D illustrate the translation of the arm 21 with respect to the transport member 40 (each moving during the loading operation) that can be used to straddle load the transport member 40 with product 25 such as shown in FIGS. 17A–17C. As shown, the transport member 40 is located at a first position P₁ and is gradually moved forward, typically in a unidirectional manner, to a second position P₂ as the arm 21 drapes or hangs the product 25 thereon. Thus, in the portion of the loading cycle illustrated, the transport member 40 moves a distance ΔP. The travel path of the transport member can be such that it is generally below and different from that of the arm 21. In certain embodiments, the arm 21 travels side to side over the transport member

24

with a constant or variable speed while the transport member 50 moves unidirectionally forward held substantially horizontally at a desired speed.

The length of the arm 21 can vary depending on various factors, such as, but not limited to, the size of the product, the forward speed of the product, the desired winding pattern and the like. In certain embodiments, the length of the arm 21 is sized to be at least the length of the transport member 40. In other embodiments, the length of the arm 21 is such that the elongate product 25 travels at least about 2–8 feet, and typically at least about 6 feet, before being discharged therefrom onto the support member 40.

The automated winder 20 may be configured to be self-supporting or free-standing and portable or free-standing and secured to the production floor relative to the related upstream and/or downstream equipment, as desired. In other embodiments, the second end portion 21b of the arm can be attached to the extruder or upstream device 10 so as to be in communication with the discharge port 10p. As such, the second end portion 21b is stationary but can be pivotally attached to the device 10. In certain embodiments, the second end portion 21b is mounted so as to be able to move bi-directionally; the mounting or attachment can be configured in any suitable manner, such as, but not limited to, a universal joint, ball joint, bearing, elastomeric joint, and the like. FIG. 23 illustrates an end view of one embodiment of the arm 21 with an end portion 21b configured to be mounted to an extruder or other upstream-positioned device. As shown, the end portion 21b is configured to be affixed to a device 10 so that it is stationary or fixed in place but allowed to translate in a bi-directional manner in response to forces introduced by the movement of the arm 21 as it, in turn moves in response to forces introduced by the winding mechanism 130 (FIG. 21).

The arm 21 can be any desired shape or configuration. The arm 21 includes a floor 21f that supports the elongate product 25. The floor 21f can be stationary or moving, or combinations thereof. For example, the floor 21f can comprise rollers, low-friction coatings or surfaces, a conveyor belt(s), and the like. In certain embodiments, the floor 21f is defined by an endless conveyor 23 (FIG. 21) that wraps around the arm 21 to continuously convey the product 25 forward and then return to the starting position by traveling back underneath the floor 21f. As shown in FIG. 20B, the arm 21 can include a channel or chute 21ch that is configured with a shape that complements the elongated product 25. For example, for a substantially circular cross-section product 25, the floor 21f may include an arcuate or semi-circular channel 21ch formed into the floor that is configured to receive a portion of the perimeter of the body of the product therein. In certain embodiments, the channel 21ch may be sized to be slightly larger, i.e., have a sectional height and/or width that is about 0.1–10% greater, than the height and/or width of the product 25. The channel 21ch may be formed over all or portions of the length thereof. The elongate product 25 can be held in the channel 21ch as it travels over the length of the arm 21.

As shown in FIGS. 20A and 20B, the arm 21 may include a cover member 21c that covers the floor 21f and encloses the elongate product 25 therein. In certain embodiments, the channel 21ch and the cover 21c may be formed from two or more matable shell members or, alternatively from a housing or a conduit that is positioned on the arm 21 to define an enclosed channel 21ch. The cover 21c may be transparent or translucent or include viewing windows along the length thereof so that a machine or operator may view or inspect product flow at desired points (or substantially all or all of

25

the travel path). The cover **21c** may be formed of a solid material. In other embodiments, a permeable or mesh-like cover (not shown) can be used.

Various automated detectors can be placed at desired locations along the arm to verify proper operation and to render an alert when an abnormality is indicated. Examples of such detectors include optical detectors (infrared or otherwise that respond to changes in visual intensity or generated light beams), flow meters, pressure meters, temperature sensors, and the like.

As shown in FIG. 17A, the winding mechanism **130** is configured to approach the arm **21** from the lower or bottom surface. As such, the winding mechanism **130** can be attached, directly or indirectly, to one or more of the bottom side (lower primary surface) and/or one or more sides (minor surfaces) of the arm **21**. FIG. 19 illustrates that the winding mechanism **130'** may alternatively be mounted to approach the arm from the topside. As such, the winding mechanism **130'** can be configured to suspend the arm **21** and may be attached, directly or indirectly, at the upper primary surface and/or one or more sides of the arm **21**. Still other embodiments can be configured so that the winding mechanism **130**, **130'** is attached via one or more end portions **21a**, **21b**, of the arm (not shown). Combinations of the attachment configurations noted above may also be used.

Referring to FIGS. 17A, 17B, and 21, the winding mechanism **130** may be attached at an intermediate position at one or more attachment locations, the attachment locations being a distance away from each of the first and second end portions **21a**, **21b**. Although the winding mechanism may be attached to the arm **21** at any desired length from the respective end portions **21a**, **21b**, in particular embodiments, the winding mechanism **130** is attached at a primary pivot location that is located inward of the ends of the arm, typically at a location that is inward at least about 20% of the length of the arm (away from each of the ends of the arm). The term "primary pivot location" describes the location on the arm **21** at which the winding mechanism drives the repetitive motion of the arm. It can be a single point contact, a plurality of points, or a region or regions, depending on the configuration of the winding mechanism itself. The attachment position/configuration, the length of the arm, and the weight of the arm and product may influence the amount of physical movement needed by the winding mechanism **130** to generate the desired translation at the end portion **21a** of the arm.

FIG. 21 illustrates one embodiment in which the winding mechanism **130** is attached at a primary pivot location **130p** that is approximately centrally located between each of the opposing ends of the arm **21**. That is, it is located to be within about 10% of the middle location of the arm **21**. In certain embodiments, as shown, the arm **21** may also include an initial enclosed entry port **221** (FIG. 23) that is configured to direct the elongated product to travel in its desired substantially linear travel path over the arm **21**. Similarly, the arm **21** may include an exit block member **222** that inhibits through passage of the elongated product **25** thereby facilitating the sideward (discharge) of the elongate product **25**. In other embodiments, the pivot or winding mechanism **130** can be located closer to the discharge port, i.e., proximate to or adjacent the product inlet port **21b**, this position may allow the arm **21** to be shortened (not shown).

Referring to FIG. 22, an exemplary embodiment of a winding mechanism **130** is shown. This figure is a side view of the device shown in FIG. 21. In this embodiment, the winding mechanism **130** comprises a four-bar linkage **33** that is mounted on a stationary mount bracket **34**. The four

26

bar-linkage **33** includes a pivotably mounted rotating link **36**, and a stationary mounted wheel **38**, a center linkage **130L** that is pivotably attached to both the pivotably mounted link **36** and the stationary mounted link **38**. In operation, the link **36** and the center link **130L** define a minor axis of motion control **41_{mm}** while the wheel link **38** and the center link **130L** define a major axis of motion control **41_{ma}**. The center linkage **130L** can include upwardly extending threads **39** that can be used to attach the winding mechanism (directly or indirectly) to the arm **21**.

The wheel **38** can be driven by a gear or shaft (not shown) to automatically turn the wheel **38** at a desired speed (constant and/or variable). Generally described, as the wheel **38** turns, the center link **130L** follows the rotation of the wheel **38**, making the center link **130L** move both laterally (indicated by the side-to-side arrows in the upper portion of the linkage) and vertically (indicated by the vertical arrows) all the while limited by the pivotably attached link **36** that limits the lateral motion of the center linkage **130L**. In this way, the winding mechanism **130** causes the arm **21** to travel through a repetitive substantially elliptical pattern **21p** as shown in FIG. 21. Of course any suitable winding mechanism can be employed, including, but not limited to, cam/follower arrangements, pistons (pneumatic or hydraulic), combinations of linkages and any of the above as well as other electromechanical configurations that can generate the desired repeated winding motion.

FIGS. 24A–24B illustrate another embodiment of a winder **20'**. As shown, the arm **21** has two spaced apart floor support mounting brackets **121**, **122**, a first one **121** positioned proximate the second end portion **21b** of the arm and another second one **122** positioned upstream of the first one **121**. The first mounting bracket **121** has a junction member **125** that is pivotably mounted to two upwardly extending arms **121₁**, **121₂**. The junction member **125** supports the arm **21** while cooperating with the winding mechanism **30** so that it allows the arm **21** to move in a multidirectional manner in response to movement of the arm as driven by the winding mechanism **30**.

FIG. 24B shows that the winding mechanism **130'** is attached to the arm **21** at a primary pivot region **130p** that is upstream of the first floor support mounting bracket **121**. The primary pivot region **130p** is at the attachment position of the winding mechanism linkage **130L** to the arm. As shown in FIG. 24C, the linkage **130L** includes a fork-like upper portion **130u** that spans the width of the arm **21** and attaches to opposing sides thereof. Similar to the embodiment shown in FIG. 22, the winding mechanism **130'** shown in FIGS. 24A–24C can be operated to cause the arm to move in a substantially elliptical rotational movement pattern. In this embodiment, the winding mechanism **130'** includes a vertically elongate linkage **130L** (such as a piston or rod) that slidably moves through linkage **136** proximate the upper portion of the vertically elongate linkage **130L** and that is connected at the lower portion thereof to a rotational member **138**. As shown by the arrows located adjacent the lower rotational member **138** in FIG. 24B, in operation, the clockwise rotation of member **138** forces the vertically elongate linkage **130L** to move forward and downward and then rearward and upward relative to the arm **21**. A counterclockwise arrangement may also be used. The movement of the vertically elongate linkage **130L** is further limited or shaped by the movement of the upper linkage **136** that pivots side to side with respect to the arm **21** (indicated by the arcuate arrows proximate the upper link **136**) as the linkage **130L** slides through the block **136b** that cooperates with the upper link **136**. The upper link **136** is pivotably mounted to a block

136b and is mounted to the platform **122** via stationary mounting bracket **34**. A spring **130s** can be mounted to the platform **122** to help control and/or dampen the movement of the winding mechanism **30'** and/or linkage **130L**. As the linkage **130L** is rotated by the lower linkage **138** it slides upwardly and downwardly through the linkage **136b** that in response pivots in lateral direction relative to the arm **21** to cause the repetitive rotation cycle.

FIGS. **24D–24E** illustrate an additional embodiment of the winding mechanism **20''**. This embodiment illustrates both a different floor or arm configuration (two overlying conveyors with an intermediate food travel path), and a variation on the winding mechanism linkage assembly. Referring to FIG. **24G**, an outer perimeter portion of the rotatable link **138** is shown attached to the lower portion of the link **130L**. As the link **138** rotates, the elongated link **130L** is directed to travel in a multidirectional motion (up and down and sideways). In operation, the rotatable link **138** is substantially constantly rotated or driven by an electric motor. One suitable motor is a $\frac{1}{4}$ HP 480V three-phase motor having about a 1750 rpm output with a 2.2 ratio.

In addition, as shown in FIGS. **24E** and **24G**, the upper link **136** can be (pivotably) attached to the block **136b** the link **136** can be (pivotably) attached to the platform **122** via a stationary mounting bracket **34**. The spring **130s** can be attached to the lower portion of the linkage **130L** (proximate the connection to the rotatable link **138**) on one end portion and the platform **122** (or bracket **34**) at a location proximate the upper link **136** at the other end portion to help control/dampen and/or stabilize the motion generated by the winding mechanism **130''**.

FIGS. **24D** and **24E** also illustrate an arm configuration that can employ two overlying aligned and vertically spaced apart surfaces that define a roof or ceiling **21r** and a corresponding floor **21f**. In certain embodiments, the roof **21r** and/or floor **21f** may be formed from one or more conveyors (shown as two spaced apart endless conveyors) **23u**, **23l**. The lower conveyor **23l** defines the floor **21f** for food or other item over the arm travel path. The two surfaces **21r**, **21f** that may be defined by conveyors **23u** (roof), **23l** (floor) can be spaced sufficiently apart so as to define a gap therebetween **23g**. The gap **23g** can be sized so as to allow both conveyor primary surfaces (those facing each other) to contact the food in opposing locations in a manner that does not deform the shape of the food as it travels between the two surfaces **21f**, **21r** and/or conveyors **23u**, **23l**, but sufficiently close so as to help guide the food in the travel direction. In other embodiments, the gap **23g** may be such that the roof, ceiling, or upper conveyor resides a distance above the food. The two conveyors **23u**, **23l** may be configured to move at the same speed. In certain embodiments, the speed of the conveyors may be operated between about 2–10 ft/sec, and in particular embodiments, at about 6.5 ft/sec linear movement. The conveyors **23u**, **23l** may be set to vary speed during operation and may be in communication with a variable speed or frequency controller from AC Tech. The drive motor may be configured similar to that described above for the winder mechanism **30**. Although described as two endless conveyors, other configurations can also be used. For example, the floor **21f** and/or roof **21r** can be formed from more than one conveyor. In other embodiments, the roof can be comprised from 2 or more conveyors creating a channel configuration having a triangle or other multi-sided configuration. The floor can also comprise a plurality of conveyors also defining a multi-sided shape (such as a triangle, open square, hexagon, and the

like). In addition, portions of the floor and/or ceiling may be configured as stationary components. Combinations of the above may also be used.

In other embodiments, the floor **21f** of the arm **21** can be configured as a “V” or “U” shape (using a conveyor surface formed in that configuration or a plurality of conveyors spaced and oriented to define the desired shape) (not shown) to help hold the food therein as it travels along the arm. Combinations of the above may also be used.

FIG. **25A** illustrates that the distal end portion **21a** of the arm **21** can be configured with an end guide **322** that helps to direct the movement of the food as it exits off the arm **21** during the winding operation as the arm moves in its desired winding motion pattern. In operation, the elongated item **25** (shown in broken line) travels through an aperture **322a** defined by the end guide **322**. The guide **322** may have an outer perimeter that is looped and defines a tongue **322t** with an open center. FIG. **25B** illustrates an alternate embodiment of an end guide **322'**. The guide **322'** includes an inwardly oriented tongue **322t'** that defines the aperture **322a'** and spaced apart prongs **322p₁**, **322p₂**. In this embodiment, in operation, the food **25** travels outwardly over the perimeter innermost portion of the tongue **322t'**. Other configurations of guides **322**, **322'** may also be used. The end guide **322**, **322'** is illustrated with the arm configuration that employs a ceiling or roof and floor **21f**, **21r**; however, the end guide **322**, **322'** is not limited thereto and may be used with any desired arm configuration. In certain embodiments, the end guide **322**, **322'** may be positioned proximate to and substantially vertically aligned with the floor **21f**. In other embodiments, the end guide **322**, **322'** may be configured to extend outwardly at a vertical level that is below the floor **21f**. In yet other embodiments, the end guide **322**, **322'** may be configured to rise above the floor **21f**.

FIGS. **26A** and **26B** illustrate exemplary winding motion patterns **21p**, **21p'** contemplated by certain embodiments of the instant invention. FIG. **26A** illustrates a pattern **21p** that is substantially constant over the winding of the length of the loading member **40** and that the arm **21** can be held substantially planar (horizontal) as it moves through the winding motion. FIG. **26B** illustrates that a variable winding motion pattern **21p'** can be generated. As shown, the winding pattern **21p'** increases or amplifies from left to right to have greater minima and maxima height **21h₁**, **21h₃** at various positions along the loading member (or between different loading members or products and/or can increase from left to right). FIG. **26B** also illustrates that the arm **21** may be inclined during the winding operation (the arm can also be declined or operated at various times to be a combination of inclined, declined, or level. In addition, the winding pattern **21p**, **21p'** can vary in other manners (shape or pattern) along the length of winding a particular carrier member **40** or vary for each or selected loading members or products.

The foregoing is illustrative of the present invention and is not to be construed as limiting thereof. Although a few exemplary embodiments of this invention have been described, those skilled in the art will readily appreciate that many modifications are possible in the exemplary embodiments without materially departing from the novel teachings and advantages of this invention. Accordingly, all such modifications are intended to be included within the scope of this invention as defined in the claims. In the claims, means-plus-function clauses, where used, are intended to cover the structures described herein as performing the recited function and not only structural equivalents but also equivalent structures. Therefore, it is to be understood that the foregoing is illustrative of the present invention and is

not to be construed as limited to the specific embodiments disclosed, and that modifications to the disclosed embodiments, as well as other embodiments, are intended to be included within the scope of the appended claims. The invention is defined by the following claims, with equivalents of the claims to be included therein.

That which is claimed is:

1. A method for supplying and loading carrier members at a loading station comprising a winding mechanism with an associated winder arm, comprising:

automatically advancing in spaced-apart relationship, a plurality of elongate carrier members having opposing first and second ends and an associated width and length, along a predetermined endless travel path to a loading station;

presenting, in serial order, the carrier members to the loading station in a substantially horizontal orientation responsive to the automatic advancing step;

discharging elongated product from a winder arm that moves in a selected pattern about the carrier member at the loading station;

straddling elongated product over a generally horizontal length of each respective carrier member at the loading station responsive to the discharging step so that portions of the elongated product are automatically serially and directly draped over the respective elongate carrier member along a length thereof, the straddling being carried out so that certain lengths of the elongated product hang from opposing sides of the carrier member to define a plurality of generally horizontal suspension segments that contact the carrier member to suspend adjacent lengths of the elongated product that hang a distance down from the opposing sides of the carrier member, the suspension segments being axially spaced apart along a length of the carrier member; and automatically advancing the carrier members loaded with the straddled product away from the loading station with the carrier members held in a generally horizontal orientation along the predetermined travel path to cause the loaded members to travel downstream of the loading station.

2. A method according to claim 1, wherein the elongate carrier member is a rod, further comprising moving the respective carrier member linearly forward while the carrier member is held substantially horizontally at a desired speed during the discharging and straddling steps, whereby the suspension segments are draped along greater than a major length of the rod, with each neighboring carrier member being generally axially aligned as the respective neighboring loaded carrier members move downstream away from the loading station.

3. A method according to claim 1, wherein the carrier members are continuously moving forward held in a generally constant horizontal orientation along the predetermined travel path during the presenting, straddling and advancing steps.

4. A method according to claim 3, wherein the straddled product on the carrier member comprises a plurality of adjacent suspension segments, the method further comprising automatically pushing or pulling the straddled product on the carrier member so that adjacent segments are translated to reside closer together over a desired length of the carrier member during the discharging and straddling step used to load a respective carrier member while a respective carrier member is moving in a direction that is downstream of the loading station.

5. A method according to claim 3, wherein a portion of the predetermined travel path is curvilinear.

6. A method according to claim 4, wherein the pushing or pulling step comprises:

moving at least one of the suspended segments on the carrier member in a predetermined direction at a first time; and then

moving another one of the at least one of the suspended segments on the carrier member in the predetermined direction at a subsequent second time to move the suspended segments closer together on the carrier member.

7. A method according to claim 1, wherein the first and second advancing steps automatically move the carrier member along the predetermined travel path, and wherein the method further comprises pivotably rotating the carrier members during the first advancing step from a first orientation where the carrier member is held generally horizontal and substantially orthogonal to the direction of travel associated with the predetermined travel path to a second orientation wherein the carrier member is held generally horizontal and substantially parallel to the direction of travel associated with the predetermined travel path.

8. A method according to claim 7, wherein the elongate carrier members automatically pivot from the first orientation to the second orientation as they advance along a portion of the predetermined travel path in advance of the loading station.

9. A method according to claim 1, wherein each support member is a substantially linear rod having a length of at least about two feet.

10. A method according to claim 8, wherein the first and second advancing steps are performed substantially continuously to serially load a plurality of carrier members.

11. A method according to claim 1, wherein the first and second advancing steps automatically move the carrier members along the predetermined travel path, and wherein the travel path is defined by an associated predetermined endless travel track having a closed perimeter with a circuit length held by a carousel, and wherein the carrier members travel less than the entire circuit length of the predetermined travel track.

12. A method according to claim 11, wherein the closed perimeter track has a generally oval shape when viewed from the top, the method further comprising individually introducing empty carrier members to the predetermined travel track at a location that is upstream of the loading station.

13. A method according to claim 12, further comprising detaching the loaded carrier members individually from the predetermined travel track at a location that is downstream of the loading station.

14. A method according to claim 11, further comprising releasably holding a first end portion of the carrier member adjacent the predetermined travel track in a manner that allows the second end portion to pivot generally horizontally toward the carousel during at least the first advancing step.

15. A method according to claim 11, further comprising permanently holding a first end portion of the elongated member adjacent the predetermined travel track in a manner that allows the second end portion to pivot generally horizontally inward toward the carousel during at least the first advancing step.

16. A method according to claim 1, wherein the discharging step releases a pre-determined length of elongated product therefrom, and wherein the straddling step is carried out so that a continuous length of product extends interme-

31

diately between adjacent ones of the generally horizontally oriented loaded carrier members as the carrier members automatically move away from the loading station in spaced apart axial alignment along the predetermined travel path.

17. A method according to claim 16, further comprising automatically cutting the intermediate lengths of the product to separate product loaded on one loaded carrier member from product loaded on another adjacent loaded carrier member.

18. A method according to claim 1, wherein the carrier member has opposing trailing and leading edge portions and the winder arm has opposing product discharge and intake portions, wherein the straddling step is carried out by moving the winder arm in a path having a perimeter associated therewith, and wherein the first and second advancing steps are carried out so that the trailing edge of the carrier member moves forward in a generally horizontal orientation from a starting location that is proximate the winder arm intake portion and travels through the perimeter of the path of the winder arm during the straddling step.

19. A method according to claim 1, wherein the elongated product is an extruded product held in a casing.

20. A method according to claim 1, wherein the elongated product is a stuffed product held in a casing.

21. A method according to claim 1, wherein the elongated product is a meat product.

22. A method according to claim 21, wherein the elongated product is a continuous length of portioned or linked meat product.

23. A method according to claim 21, wherein the elongated product is a contiguous length of non-chain linked meat product.

24. A method according to claim 1, wherein the elongated product is a non-cased food product.

25. A method according to claim 6, wherein the first and second moving steps are carried out by serially pushing successive spaced apart suspended segments forward along the carrier member.

26. A method according to claim 6, wherein the first and second moving steps are carried out by serially pushing non-successive spaced apart suspended segments forward along the carrier member.

27. A method according to claim 6, wherein the first and second moving steps are carried out by directly contacting consecutive suspended segments.

28. A method according to claim 6, wherein the first and second moving steps are carried out by directly contacting a subset of the suspended segments.

32

29. A method according to claim 1, wherein the winder arm has a length with opposing product intake and discharge end portions, wherein the carrier member is an elongate member with opposing leading and trailing edge portions, and wherein the advancing and presenting steps are carried out to automatically serially position respective carrier members so that at the loading station at a beginning of the straddling step, the leading edge portion of the carrier member is downstream of the discharge end portion of the winder arm and the trailing edge portion of the carrier member is upstream of the discharge end portion of the winder arm, then during the straddling step each respective carrier member travels in a generally straight line for a distance that is at least a major portion of the winder arm length.

30. A method according to claim 29, wherein the winder arm travels over and side to side of the carrier member during the straddling step.

31. A method according to claim 30, wherein the winder arm loops the elongate product around the carrier member during the straddling step.

32. A method according to claim 29, wherein the carrier member is an elongate rod that is held generally horizontally and axially aligned with the direction of forward movement during the straddling step.

33. A method according to claim 1, wherein the carrier member predetermined travel path is defined by at least a portion of a mechanized curvilinear endless travel circuit having a perimeter that includes opposing first and second arcuate portions with linear portions therebetween, wherein the winder arm is positioned outside the perimeter of the endless travel circuit proximate a selected arcuate portion thereof, and wherein the advancing step comprises automatically moving the carrier members in concert so that as respective corner members move away from the selected arcuate portion of the endless travel circuit, a major portion of the carrier member is located downstream of a forward edge portion of the winder arm.

34. A method according to claim 1, wherein the carrier member is devoid of hooks.

35. A method according to claim 1, wherein the carrier member is a substantially straight rod having a length of at least about 2 feet, and wherein the winder arm has a length that is at least the length of the rod.
